

Developing a non-invasive field method for monitoring thyroid hormone concentrations in black rhinoceros, Grevy's zebra and

Sian Wilcox, Rebecca Mogeey, Sue Walker
African elephant

Background

- Thyroid hormones (T3 and T4) are involved in a number of important physiological processes
- Thyroid hormones have been shown to decrease in response to diminished food intake^{1,2}
- May explain why some populations in situ perform better than others

2. Wasser, S.K. et al. (2010) *General and Comparative Endocrinology* 168, 1-7

Hawkins, E. et al (2015). *Journal of Wildlife Diseases* 51

Why use poo?

- Non-invasive
- Easy to collect
- Broad time frame

Poo and thyroid hormones

In order to get the thyroid hormones out of the faeces it must first be extracted

- The concentration of hormone is measured using a total T3 enzyme immunoassay (EIA)

Extraction process

- Faecal samples are collected as part of standard husbandry routine
- Stored at -20°C

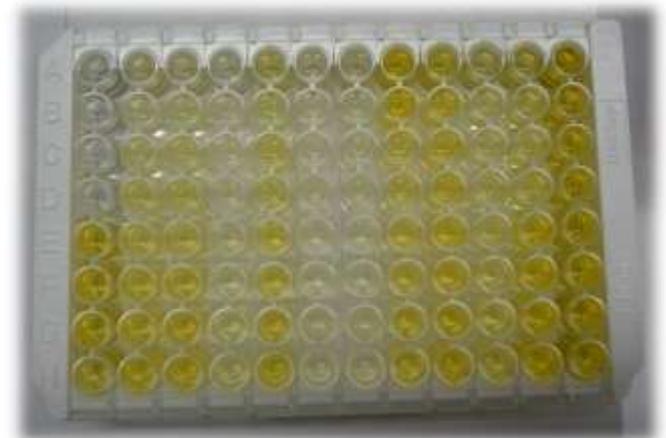

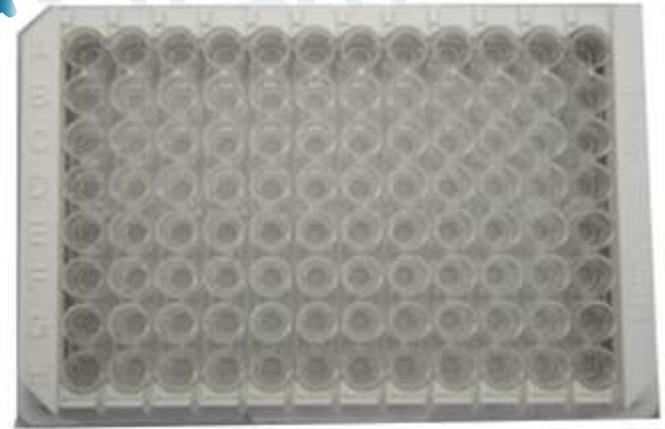

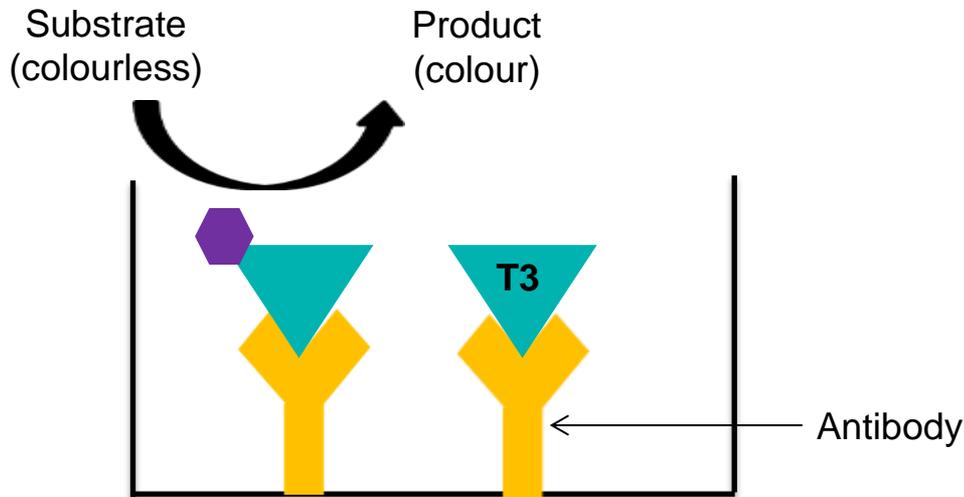

Laboratory method:

0.5g faeces + 5ml 90% methanol → spun → dried → re-suspended 1ml 100% methanol

Enzyme Immunoassay (ETA)

- Used to determine the concentration of T3 hormone in our samples

The problems with poo

- The current lab method requires samples to be stored at -20°C
- BUT may not have access to electricity/equipment in the field
- Cartridges have successfully been used to store faecal samples for analysis of reproductive and stress hormones¹

Field extraction method:

0.5g faeces + 90% methanol → **diluted and loaded onto cartridge** → **eluted with 5ml 100% methanol** → **dried and re-suspended**

Aims & Hypotheses

The main aims of the study were:

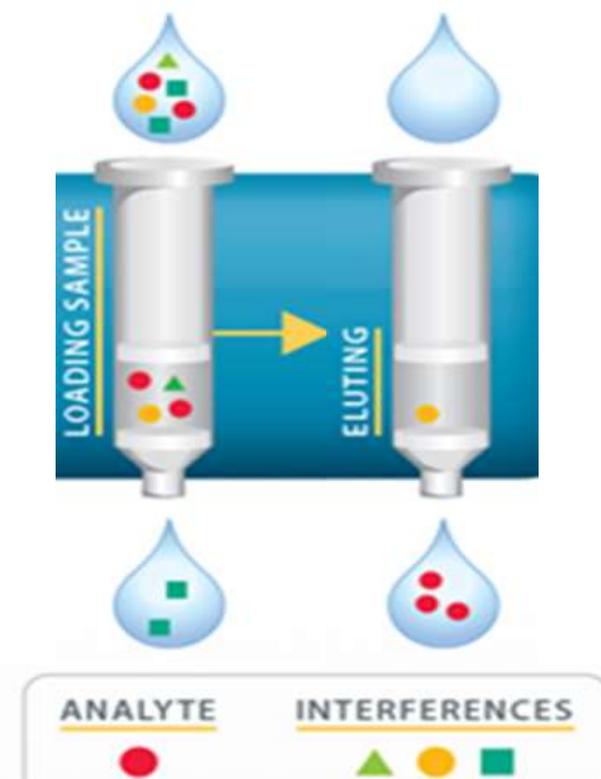

- to develop a non-invasive field method for extracting and storing faecal samples for analysis of thyroid (T3) hormone
- to validate the use of a total T3 EIA for measuring T3 in the faeces of megaherbivores (black rhinoceros, Grevy's zebra, African elephant)
- to produce results that are comparable with the standardised laboratory method

It was hypothesised that:

1. T3 recovery will be observed at >40% methanol solution
2. T3 recovery would be improved by using acid to elute and/or plastic tubes to dry samples
3. Lab extracted and field extracted samples will be comparable

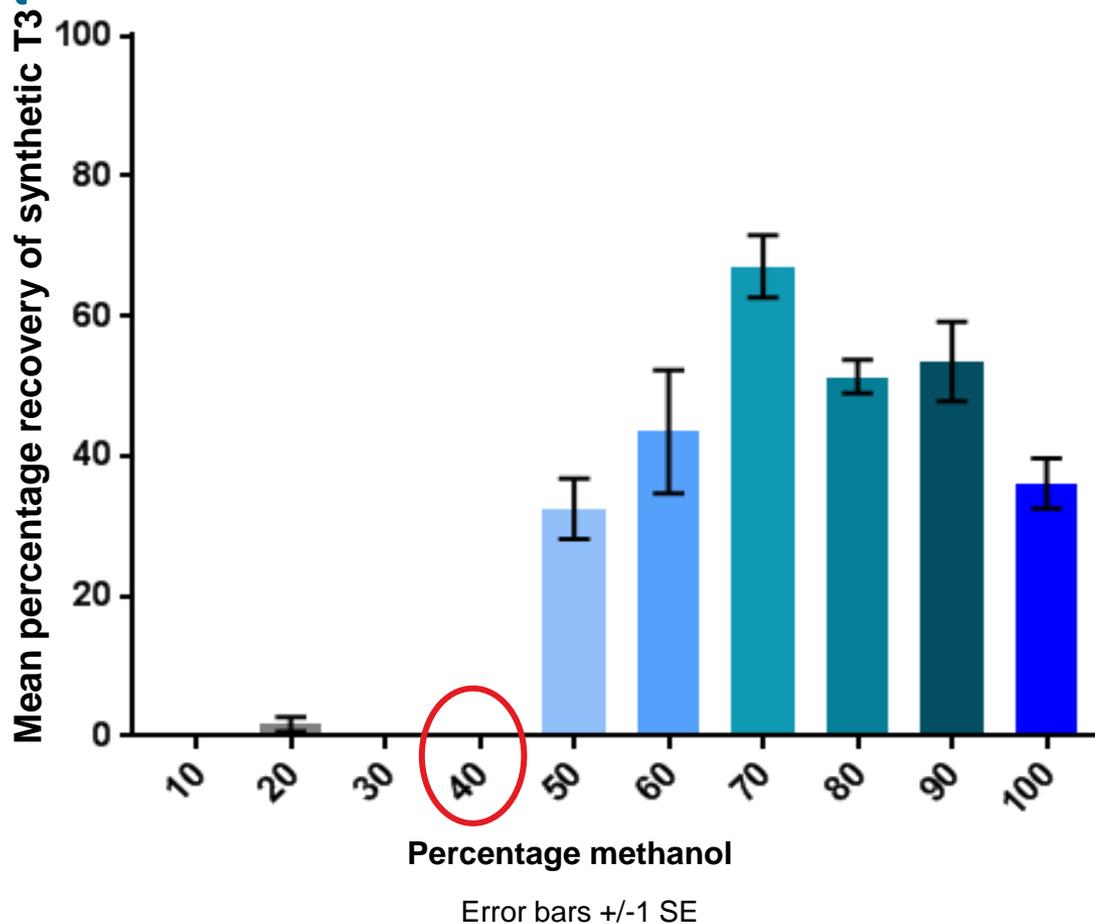

At what solvent concentration does T3 elute from the column?

- Need hormone to stick to cartridge
1. A known concentration of synthetic T3 hormone was loaded onto cartridges
 2. Cartridges were eluted with increasing concentrations of methanol (10%-100%)
 3. Percentage recovery of hormone was measured using a total T3 enzyme immunoassay

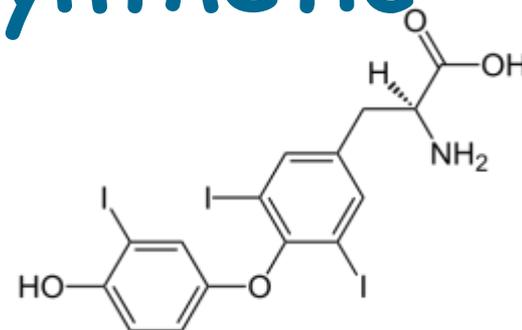

Results - Hypothesis 1

Optimal loading concentration of solvent*

Improving recovery of synthetic T3 hormone

- Low recovery of synthetic T3 was observed (~65%)
- Possibly due to T3 molecules interacting with silanol groups in the glassware used and/or in the cartridges
- A known concentration of synthetic T3 was loaded onto cartridges
- Cartridges were eluted with increasing concentrations of methanol (10%-100%)
- Liquid was evaporated off in either glass tubes or plastic tubes
- A known concentration of synthetic T3 was loaded onto cartridges
- Cartridges were eluted with acidified methanol
- Liquid evaporated in plastic tubes

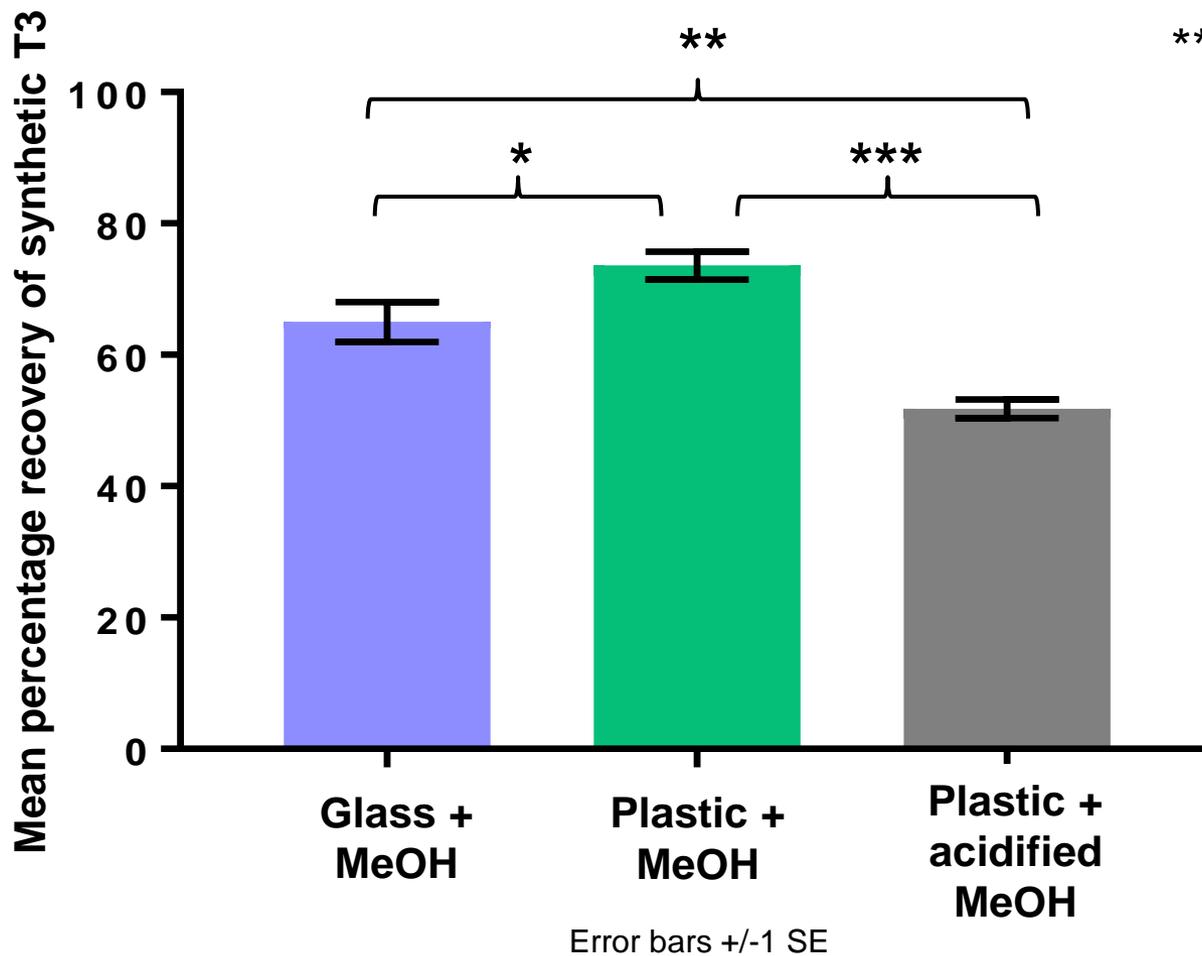

Results - Hypothesis 2

Optimising synthetic

T3 recovery
One-way ANOVA, Turkey's multiple comparisons test

* $P=0.0406$
** $P=0.0007$
*** $P<0.0001$

Chemical validation of three species

Parallelism

- A pooled faecal sample was created
- Run in parallel with standards of known concentrations
- Determines whether the assay is measuring T3 in the samples

Recovery

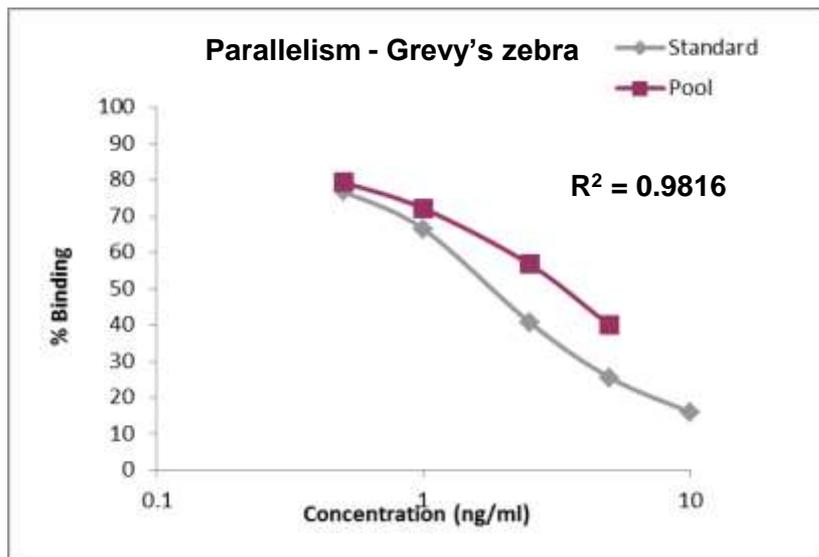

- Standards were spiked with the pooled sample
- Checks that the observed concentration of T3 corresponds to the true concentration
- Tests for interferences from other compounds

Study animals

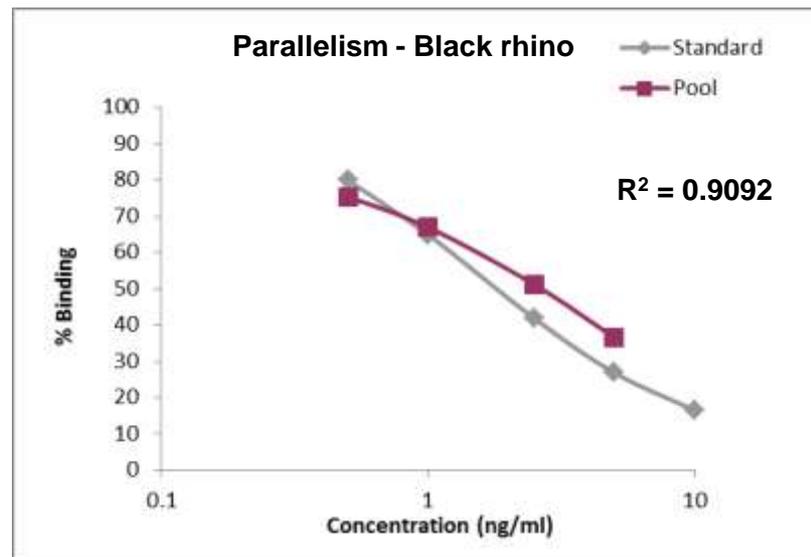

- 120 samples were collected from 13 adult female pregnant and non-pregnant megaherbivores, consisting of:
 - 4 black rhinoceros (*Diceros bicornis*)
 - 3 Grevy's zebra (*Equus grevyi*)
 - 6 African elephants (*Loxodonta africana*)

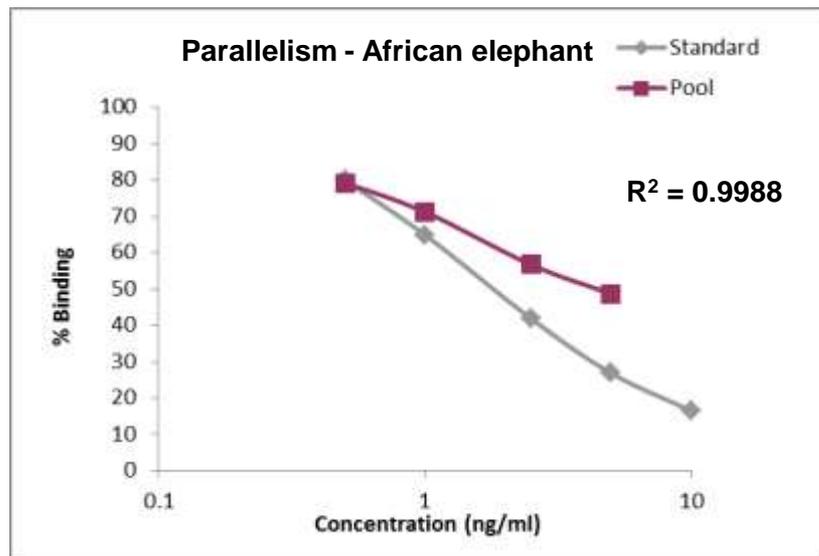

Results - chemical validation

Recovery: $R^2 = 0.9985$

Recovery: $R^2 = 0.9780$

Recovery: $R^2 = 0.9968$

For parallelism to be significant:

- $R^2 > 0.9$
- X variable (slope) > 0.5
- Intercept is approximately 0

Comparison of lab and field method

- Faecal samples were split into two sub-samples
- Extracted in parallel by either the lab method or the optimal field method
- T3 concentration were quantified using a T3 enzyme immunoassay

Laboratory method:

0.5g faeces + 5ml 90% methanol → spun + dried → re-suspended in 100% methanol

Field method:

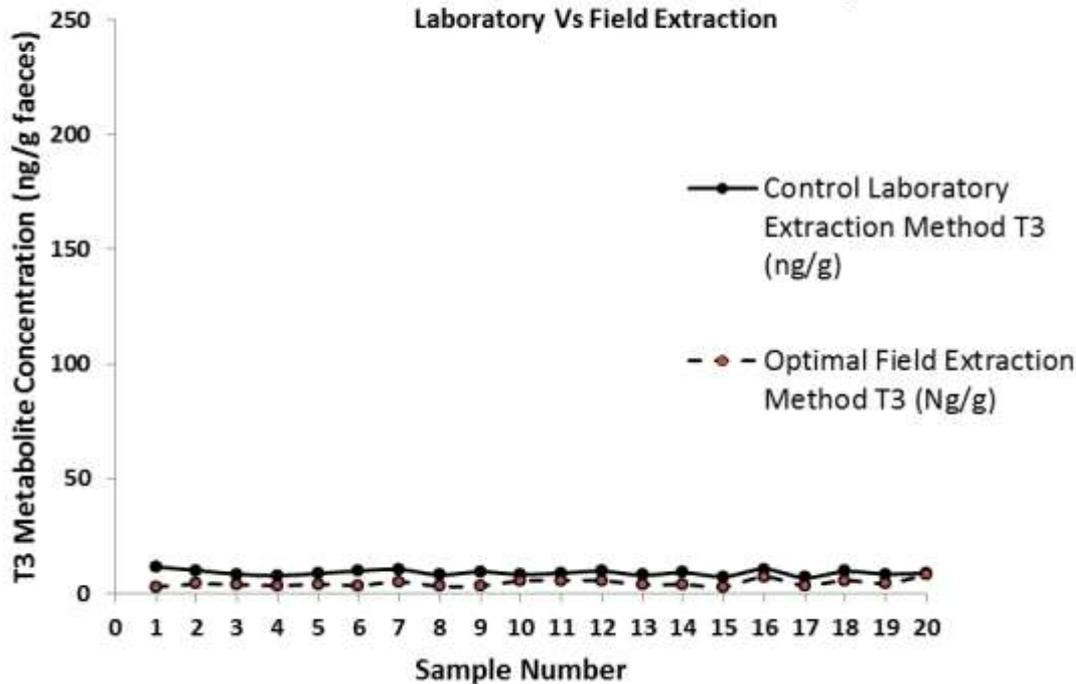

0.5g faeces + 5ml 90% methanol → diluted and loaded onto cartridge → eluted with 5ml 100% methanol → dried and re-suspended in 100% methanol

Results - Hypothesis 3

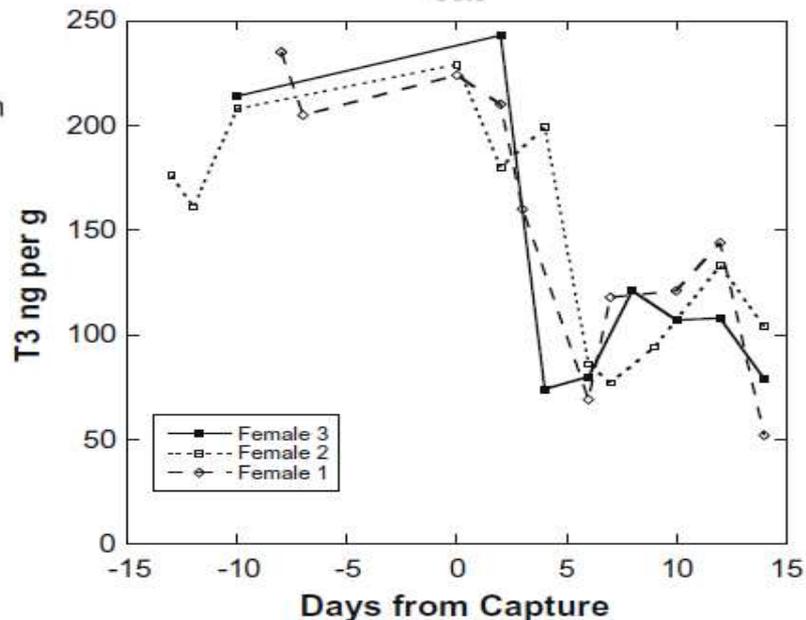

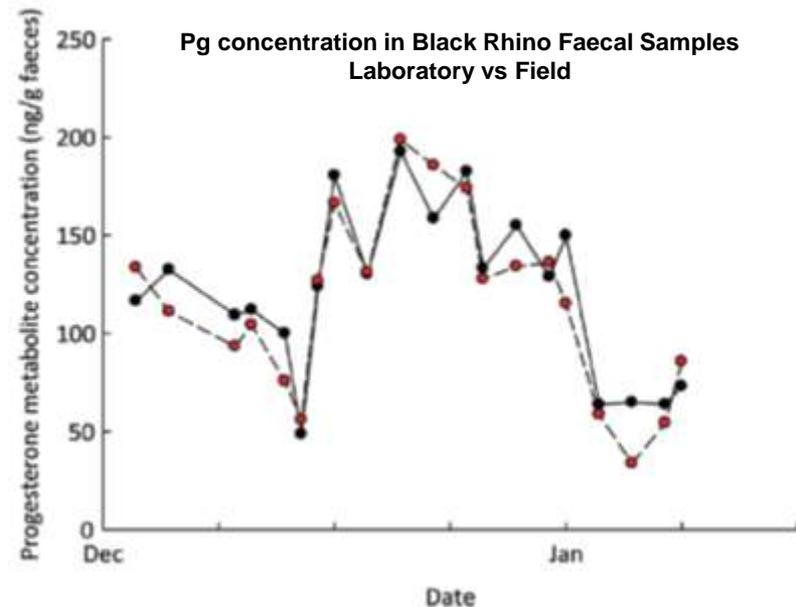

Lab vs Field - Grevy's Zebra

Linear regression, Pearson's correlation

T3 concentration in Grevys Zebra Faecal Samples Laboratory Vs Field Extraction

$r = 0.455, P = 0.044, n = 20$

Conclusions

- T3 hormone recovery was observed at >40% methanol
- Use of plastic tubes significantly improved recovery of synthetic T3 ($p < 0.05$) but acid significantly reduced recovery of synthetic T3 ($p < 0.05$)
- The use of a total T3 EIA was chemically validated to measure faecal T3 in three megaherbivore species
- With further development this method could be used to:
 - Monitor T3 concentrations in a variety of megaherbivores
 - Determine how nutritional status of different areas is impacting on the reproductive success of populations in situ
 - Inform conservation efforts and population management decisions on a continental scale
